Section: Genital (female) imaging
Area of Interest: Genital / Reproductive system female
Procedure: Imaging sequences
Technique: MR
Special Focus: Neoplasia Case Type: Clinical Cases
Authors: Monteiro V, Cunha TM, Saldanha T
Patient: 23 years, female

Clinical History:

A 23-year-old woman was admitted for progressive pelvic pain, weight loss, fever and enlargement of abdomen that had started one month before admission. On physical examination a large pelvic painful mass was palpated. Laboratory studies revealed anaemia, thrombocytopenia and moderate elevation of levels of CA-125 and LDH.

Imaging Findings:

Ultrasonography revealed bilateral solid adnexial masses and a MRI was performed to better characterize these lesions. MRI revealed bilateral lobulated, heterogeneous, solid ovarian masses which were hypointense on T1-weighted images (WI) (Fig. 1) and of intermediate signal intensity on T2-WI with small, round, high signal intensity lesions in the periphery, consistent with follicles (Fig. 2). The lesions extended up to the level of the liver (Fig. 3) and small amount of ascites and moderate right hydronephrosis were also seen (Fig. 4). After intravenous gadolinium administration the lesions enhanced moderately (Fig. 5). No signs of peritoneal carcinomatosis were found. The main differential diagnoses were lymphoma, metastases, immature germ cell tumor and granulocytic sarcoma. Bone marrow biopsy was performed and there was no evidence of involvement by non-Hodgkin lymphoma. Preoperatively CT did not revealed generalized lymphadenopathy. Total abdominal hysterectomy and bilateral adnexectomy were performed and pathological diagnosis was bilateral ovarian Burkitt lymphoma. Presently the patient is receiving combination chemotherapy treatment.

Discussion:

Involvement of the ovary by malignant lymphoma is a well-known late manifestation of disseminated nodal disease. However, primary ovarian lymphoma is very rare and accounts for only 1.5% of ovarian neoplasms and 0.5% of non-Hodgkin's lymphomas [1]. This low incidence of ovarian involvement by lymphoma is thought to be due to the fact that there is no lymphoid tissue in the ovary and it has been suggested that the tumour originates from rare lymphocytes that are dispersed throughout the ovarian stroma and within ovarian follicles and corpora lutea [2].

The most common type of lymphoma involving the ovary is diffuse large B-cell lymphoma [3]. Burkitt's lymphoma is a very rare highly undifferentiated type of non-Hodgkin's lymphoma derived from B-lymphocyte. It is a rapidly growing lymphoma that occurs mostly in children, and has been described in HIV/AIDS patients.

The majority of primary abdominal lymphoma present with pelvic complaints and common symptoms are abdominal masses and menstrual abnormality.

The diagnosis of primary ovarian lymphoma should be considered in the presence of large bilateral solid ovarian
mass, although no specific imaging features can differentiate Burkitt's lymphoma from other neoplasms and only histopathological finding after surgery treatment confirms the diagnosis.

Some criteria for the diagnosis of primary ovarian lymphoma have been suggested [4], and the diagnosis can only be made if at the time of diagnosis, the tumor is confined to the ovary without any evidence of lymphoma elsewhere, except if spread has occurred to immediately adjacent lymph nodes or infiltrates immediately adjacent structures. Also, the peripheral blood and the bone marrow should not contain any abnormal cells and several months should have elapsed between the appearances of the ovarian and the extra-ovarian lesions.

MRI provides better characterization of ovarian masses than ultrasound [5]. The MRI findings usually include solid bilateral masses, with low signal intensity on T1-weighted images and mildly high signal intensity on T2-weighted images. Lesions tend to show mild to moderate contrast enhancement after intravenous gadolinium administration. CT is the preferred imaging modality for lymphoma staging in the chest, abdomen, and pelvis as well as in other nodal lymphomas. Bone marrow biopsy is also mandatory for staging.

According to previous reports in literature, the treatment principles and the prognosis are similar as that of other nodal lymphomas [6] and tend to be better than for other primary tumors of the ovary.

**Differential Diagnosis List:** Bilateral ovarian Burkitt lymphoma, Ovarian metastases, Immature germ cell tumour, Granulocytic sarcoma

**Final Diagnosis:** Bilateral ovarian Burkitt lymphoma
